Sadono Sukirno, 2000, Pengantar Ilmu Ekonomi, PT. Asahra.Q: Efficient sorting algorithm for transposition The task: Given a list of integers, output its transposition in the most efficient way possible (faster than $O(N^2)$ in this case) I've thought about doing this by comparing the list of numbers to a matrix and transposing it. Since the list must be sorted, we can simply transpose the matrix again. I've been doing a lot of research on algorithms and have found sorting algorithms such as Merge Sort, QuickSort, TimSort. But they all are $O(N^2)$ and are better suited for small lists, than large ones, since they can easily break down when sorting small lists. Is there an algorithm for this that is less efficient than $O(N^2)$? I know how to convert the input list into an array, and how to convert it into the transposition of the matrix. The big question is how to do that in the most efficient way possible. A: This will be a linear time algorithm, and for large values of N it will be more efficient than an $O(N^2)$ algorithm. Step 1 - sort the list Step 2 - Reverse the list Step 3 - Reverse the list again Step 4 - Reverse the list again Step 3 is the trickiest, because it involves going "back and forth". Ideally, you can pre-compute a sorted array, and just swap that with the original array. A: A linear time solution would be to sort the list in place using a binary search tree 2d92ce491b
