In several clinically significant conditions haemoglobin is sequestered to red cell membranes or transformed into intracellular inclusions. Both of these reactions result in a decreased availability of oxygen to the tissues and an increased release of toxic products which can damage the renal tubules or cause death. The formation and function of aggregates of haemoglobin are being examined under conditions of increased oxygen affinity (increased P50). Techniques are being developed to quantify and identify such aggregates in the cell and in the blood. These studies will help to elucidate the biochemical defects which occur under pathological conditions and will enhance our understanding of oxygen binding properties of haemoglobin.The present invention relates to a new and distinctive corn inbred line, designated LH151
